🎯 General context

Network incidents were often identified only after their impact had already escalated. By the time Carrier stakeholders became aware of a problem, support channels were frequently overwhelmed with customer reports, making customer contact volume an informal detection mechanis

Problem statement

The current process is reactive. Although Holafly has access to network-quality data, the existing dashboard presents aggregated technical metrics that require manual filtering and interpretation. It does not clearly communicate when an incident is happening, its severity, where it is occurring or how many travellers may be affected.

As a result, teams cannot easily distinguish a widespread outage from a localized degradation or prioritize the destinations requiring immediate attention.

Impact

Late detection increases the number of affected travellers, overloads Support, delays coordination with network partners and allows problems to become visible through complaints, NPS and refunds before an operational response begins.

Opportunity

The nSpire feed provides near-real-time network signals that can help Holafly move from reactive to proactive incident detection. The opportunity is to surface potential incidents through Slack and provide an incident-focused dashboard where Carrier stakeholders can prioritize, investigate and track recovery before customer impact continues to grow.
